1 Description of the language

Sushi++ is a mostly functional language, enhanced with a few features belonging to the imperative paradigm.

1.1 Features

Here is our list of features, presented in a decreasing order of priority:

- 1. Anonymous function,
- 2. Closure: a function will be able to capture a variable or a function from a higher scope,
- 3. Delimiter of end of line: \n ,
- 4. Full type inference,
- 5. Type hinting: allow the user to specify the type of a function parameter,
- 6. Built-in datastructures: array, list and tuple,
- 7. Usage of language C to use a few function,
- 8. Simple garbage collector: to clean the memory after the usage of built-in datastructures.
- 9. Packages: functions could be declared in namespaces/packages.

1.2 Keywords

The keywords of this language are inspired from the lexical field of sushi food. We have:

- maki: declaration of a variable or a named function.
- soy: declaration of an anonymous function.
- roll: while loop.
- for: for loop.
- continue, break: loop iteration control.
- if-elseif-else: conditional structure.
- menu: switch structure.
- nori: return.
- to: list "constructor".
- $\bullet \ \ \mathrm{Types:} \ \mathtt{int}, \, \mathtt{float}, \, \mathtt{string}, \, \mathtt{array}, \, \mathtt{list}, \, \mathtt{tuple}$
- mat: define a package. This is not taken into account yet, but will be considered if time allows it.

The Sushi++ comments are single line comments and begin with the character '\$'.

1.3 Built-in datastructures

We consider to implement 3 types of datastructure of which the behavior will be defined based on 3 properties:

- **Structure mutability**: it is mutable if items can be added and removed after the creation of the datastructure,
- Item mutability: it is mutable if the items can be changed after the creation of the datastructure,
- "Multityping": if the datastructure can contain elements of different types.

Name	Structure mutability	Item mutability	Multityping
array	Mutable	Mutable	Single type
list	Immutable	Immutable	Single type
tuple	Immutable	Mutable	Multiple types

Table 1: Properties of the datastructures

1.4 Operators

We decided to provide our language with the following operators : $% \left\{ \left\{ 1\right\} \right\} =\left\{ 1\right\} =\left\{$

- The assignment operators : = for a variable, : for a function,
- Some arithmetic operators: *, +, -, /, **, %,
- Some logic operators : ||, |, &, &&, ^,!
- Some comparison operators : ==, <, >, <=, >=,
- Some special operators: incrementation: ++, decrementation: -- and concatenation: .
